

A customizable multiplex protein microarray for antibody testing and its application for tickborne and other infectious diseases

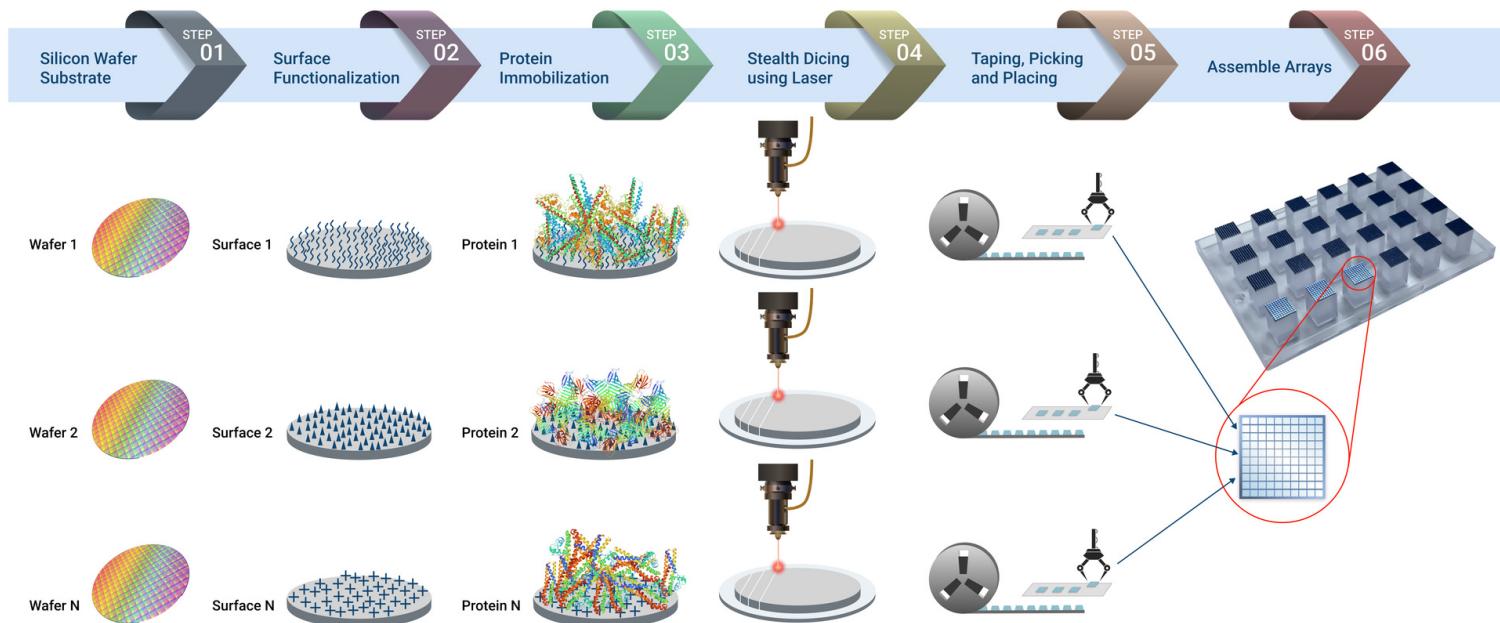

A tick can carry and pass on multiple infectious agents in a single bite. Testing needs to be for a comprehensive broad panel of all possible infections at the outset to avoid delayed diagnosis. Additionally, prolonged exposure to Lyme and its co-infections can compromise the immune system, rendering individuals more susceptible to infections like Epstein Barr virus and opportunistic pathogens which also needs to be tested in cases of chronic infection. The tickborne zoomer is a product to meet this requirement.

In this publication, we present the comprehensive evaluation of the Tickborne Zoomer with various associated infections involving more than 2,900 individuals. The study presents the key performance metrics of the Tickborne immunochip's analytical performance, including precision, sensitivity, reportable range, linearity, along with matrix equivalency studies, paving the way for a paradigm shift in tickborne disease diagnosis. Additionally, the report presents striking clinical sensitivity and specificity findings, particularly in the combined evaluation of IgM and IgG, showcasing a remarkable 100% accuracy for multiple infectious agents (Table on page 2). Image below is of chips on a single pillar containing one chip for one antigen. A patient's serum is tested against all the chips at the same time. Current antigens and future antigens are indicated.

Pathogen	Pathogen Antibodies							Gold Standard [34-48]	
	IgM		IgG		IgM+IgG				
	Sensitivity (%)	Specificity (%)	Sensitivity (%)	Specificity (%)	Sensitivity (%)	Specificity (%)	Sensitivity (%)	Specificity (%)	Sensitivity (%)

Individual wafers were cut into 0.70 x 0.70mm² microchips for each antigen. These microchips were placed on carrier tapes using a die-sorting system and then loaded onto a high-throughput surface mount technology (SMT) component placement system. Ultimately, 24 pillar plates were used to mount these microchips, with each pillar containing 87 microchips designated for different antigens, including recombinant protein, peptide, or whole cell sonicates.

This research involved collaboration from over 25 renowned global researchers, including the CDC, NY Department of Health -Parasitology Laboratory/Wadsworth Center (NYSDOH), universities, and private clinics.

Sample Cohort			
Pathogen	No.	Source (scientist/company)	Basis of Diagnosis
Borrelia burgdorferi	298	CDC, Private Clinics	RT-PCR, Physician
Babesia microti	70	Parasitology Laboratory, Wadsworth Center (NYSDOH)	RT-PCR, Blood Smear
Babesia microti	118	Seracare, Boca Bio, Private Clinics	Serology, RT-PCR

B. bissettiae (<i>I.scapularis</i> , <i>I. persulatus</i> , <i>I. spinipalpis</i> , <i>I. pacificus</i>)	Whole cell sonicate	Cytomegalovirus	EIA, gB, p150, p28, p52, pp65, p38
B. lusitaniae (<i>I. ricinus</i>)	Whole cell sonicate	Epstein Barr virus	EA, EBNA1, VCA gp125, p18, p23
B. valaisiana (<i>I. ricinus</i> , <i>I. nippensis</i> , <i>I. columnae</i>)	Whole cell sonicate	Parvovirus B19	VLP VLP2,VLP VP1/VP2 Co Capsid
B. yangtzensis (<i>I. granulatus</i> , <i>I. nipponensis</i>)	Whole cell sonicate	Toxoplasma gondii (Multiple Ticks)	WCS, MIC3, p24, p29, p30
B. turcica (<i>H. aegypticum</i>)	Whole cell sonicate	HSV-1	Whole cell sonicate
Babesia microti (<i>I. ricinus</i> , <i>I. scapularis</i> , blood transfusions, perinatal)	IRA, p32, p41, WCS	HSV-2	Whole cell sonicate
		HHV-6	Whole cell sonicate

The Immunochip assay for antibody detection is a highly efficient and automated process. Serum samples are diluted at a 1:20 ratio and incubated on a pillar plate at room temperature for 1 hour. Subsequent steps involve washing and incubation with secondary antibodies (Goat Anti-Human IgG HRP and Goat Anti-Human IgM HRP) followed by chemiluminescent substrate addition and imaging. To enhance IgM sensitivity, proprietary assay components are used to strip IgG before IgM testing.

This multiplex antibody detection relies on chemiluminescent immunoassay and requires less than 200 µL of serum. Liquid handlers are programmed to handle sample dilution, multi-step incubation, and multi-solution washing, allowing for the analysis of 192 individual specimens in just 2 hours. Chemiluminescent signals from each probe are converted into intensity plots using specialized software. This automated antigen detection method significantly reduces turnaround time, labor costs, and the need for manual handling and subjective interpretation of results when compared to traditional two-tiered testing methods recommended by the CDC. Additionally, all antibodies are detected in a single run, streamlining the process further.
